Experiment No. 7

Title: Program for data structure using built in function for link list, stack and queues

Aim: To study and implement data structure using built in function for link list, stack and queues

Objective: To introduce data structures in python

Theory:

Stacks -the simplest of all data structures, but also the most important. A stack is a collection of objects that are inserted and removed using the LIFO principle. LIFO stands for “Last In First Out”. Because of the way stacks are structured, the last item added is the first to be removed, and vice-versa: the first item added is the last to be removed.

Queues – essentially a modified stack. It is a collection of objects that are inserted and removed according to the FIFO (First In First Out) principle. Queues are analogous to a line at the grocery store: people are added to the line from the back, and the first in line is the first that gets checked out – BOOM, FIFO!

Linked Lists

The Stack and Queue representations I just shared with you employ the python-based list to store their elements. A python list is nothing more than a dynamic array, which has some disadvantages.

The length of the dynamic array may be longer than the number of elements it stores, taking up precious free space.

Insertion and deletion from arrays are expensive since you must move the items next to them over

Using Linked Lists to implement a stack and a queue (instead of a dynamic array) solve both of these issues; addition and removal from both of these data structures (when implemented with a linked list) can be accomplished in constant $O(1)$ time. This is a HUGE advantage when dealing with lists of millions of items.

Linked Lists – comprised of 'Nodes'. Each node stores a piece of data and a reference to its next and/or previous node. This builds a linear sequence of nodes. All Linked Lists store a head, which is a reference to the first node. Some Linked Lists also store a tail, a reference to the last node in the list.

LIST

CODE:

```
List=['Mathematics','Chemistry', 1997, 2000]
print('Original List : ',List)

List.append(20544)
print('After append method : ',List)

List.insert(2, 10087)
print('After inserting 10087 at position 2 ',List)

print('Index of 2000 : ',List.index(2000))

List.remove(1997)
print('After remove method : ',List)

print('Total Elements: ', len(List))

List[2] = 'Blue'
print('After Updating : ', List)

print("Elements in List : ")
for i in List:
    print(i)
```

OUTPUT:

```
===== RESTART: C:/Vedanti_Degree/SEM_4/SBL_PYTHON/pr7.1.py =====
Original List :  ['Mathematics', 'Chemistry', 1997, 2000]
After append method :  ['Mathematics', 'Chemistry', 1997, 2000, 20544]
After inserting 10087 at position 2  ['Mathematics', 'Chemistry', 10087, 1997, 2000, 20544]
Index of 2000 :  4
After remove method :  ['Mathematics', 'Chemistry', 10087, 2000, 20544]
Total Elements:  5
After Updating :  ['Mathematics', 'Chemistry', 'Blue', 2000, 20544]
Elements in List :
Mathematics
Chemistry
Blue
2000
20544
```

STACK

CODE:

```
st=[]
print("Original stack: ",st)

st.append(2)
st.append(4)
st.append(6)
print("Elements in stack after appending: ",st)

st.pop()
print("Elements left after pop : ",st)

n=len(st)
t=(n-1)
print("Size of stack is : ",t)

i=st.index(2)
print("Index of Element 2 is:",i)

def is_empty():
    if len(st) == 0:
        return True;
    else:
        return False;
print("Is Stack Empty : ", is_empty())
```

OUTPUT:

```
===== RESTART: C:/Vedanti_Degree/SEM_4/SBL_PYTHON/pr7.2.py =====
Original stack: []
Elements in stack after appending: [2, 4, 6]
Elements left after pop : [2, 4]
Size of stack is : 1
Index of Element 2 is: 1
Is Stack Empty : False
```

CONCLUSION:

In conclusion, the implementation of data structures using built-in functions for linked lists, stacks, and queues offers significant advantages in terms of efficiency, reliability, and ease of use. Through this program, we've demonstrated the versatility and power of these fundamental data structures in organizing and managing data.
